Data Scraping using Selenium

This guide will explain how to include "Selenium" related packages to use Selenium Chrome driver to simulate actions in chrome browser and do different types of actions in it. Also it explains how to extract information from a web page. This tutorial is only for learning purposes.

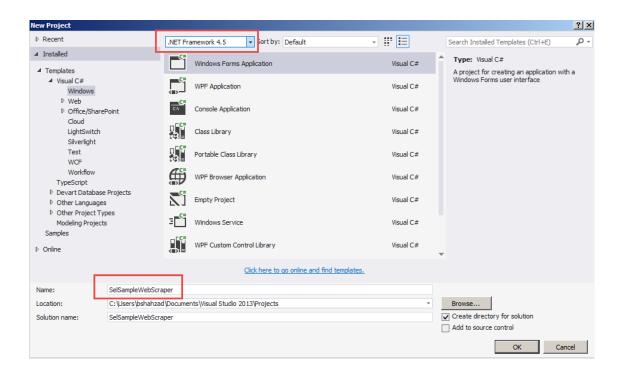

Selenium is an "Automation Testing" tool.

Version	Last updated	Comments	Modified By
V1.0	22-04-2016		Bilal Shahzad

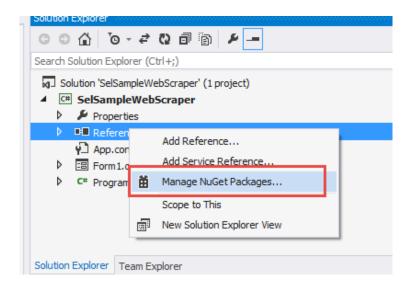

Here we are going to build a simple windows application which will use "Selenium" APIs and will extract basic job information from "rozee.pk" site.

Walkthrough

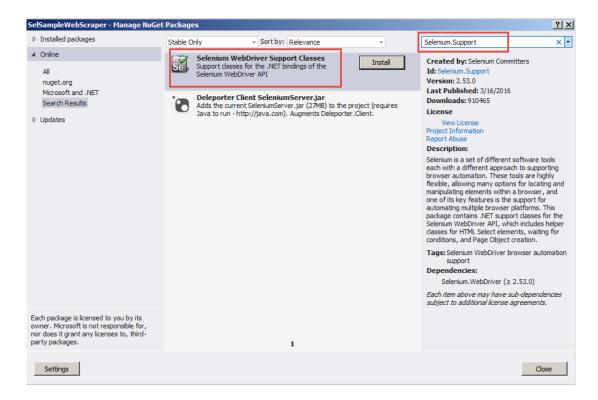

1- Create a new "Windows Forms" application with .NET Framework 4.5.

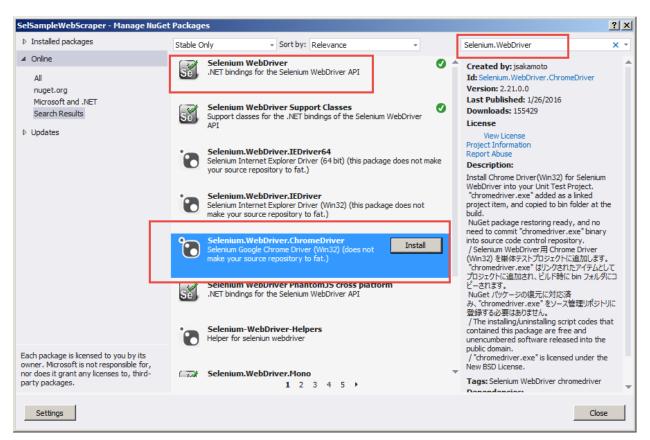

2- Now we need to add some references to access "Selenium" API. Right click on "References" and select "Manage NuGet Packages..."

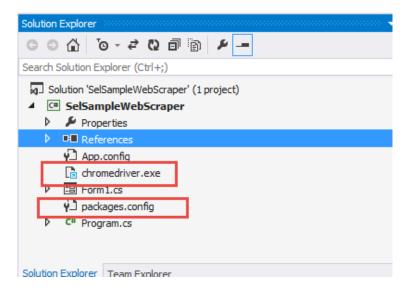

3- In search box type "Selenium. Support" and Install the package as highlighted in following screenshot.

4- In search box type "Selenium. WebDriver" and Install the packages as highlighted in following screenshot.

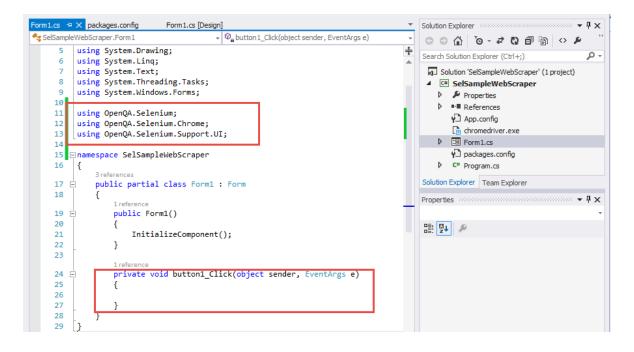

5- You will see "chromdriver.exe" and "Packages.config" file.

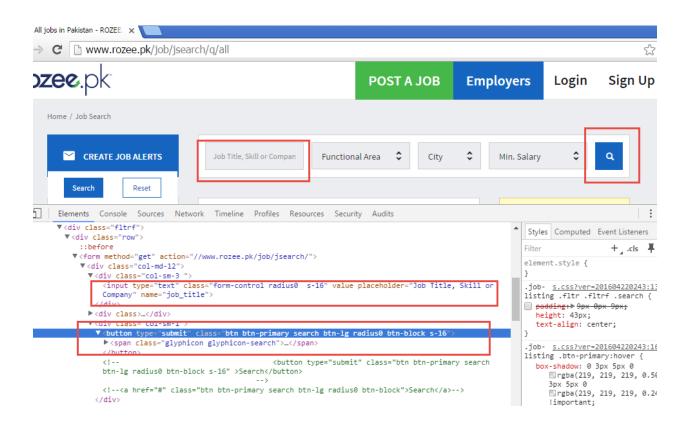

6- In "Packages.config", you will see following packages are added. Also check the reference of DLLs shown in right side panel.

7- Now add a button on a form and generate click event of it. In Code, add the reference of namespaces as shown below.

8- We are going to scrap data from following http://www.rozee.pk/job/jsearch/q/all. On this link, we'll provide some text to type in highlighted textbox. Also HTML of textbox and button is highlighted to access them via code using CSS selector approach.

9- Add following code in button click event handler. This code will open a chrome browser and will navigate it to the given URL. After page is loaded, it will send keys (i.e. software engineer) to specific text box.

```
orm1.cs + × packages.config
                         Form1.cs [Design]

    Solution Explorer

tselSampleWebScraper.Form1
                                               → ♥ button1_Click(object sender, EventArgs e)
                                                                                                   20
                                                                                                   Search Solution Explorer (Ctrl+;)
    21
                       InitializeComponent();
                                                                                                    Solution 'SelSampleWebScraper' (1 pro
    22
                   }

▲ SelSampleWebScraper

                                                                                                      Properties
                                                                               URL to
                   1 reference
                                                                                                      ▶ ■·■ References
                                                                             navigate
                   private void button1_Click(object sender, EventA
    24
                                                                                                         App.config
                                                                                                         chromedriver.exe
    25
                                                                                                      Form1.cs
                        String url = "http://www.rozee.pk/job/jsearch/q/all";
    26
                                                                                                         packages.config
    27
                                                                                                      C# Program.cs
                                                                       Navigate to URL
                        IWebDriver driver = new ChromeDriver();
    28
    29
                       driver.Navigate().GoToUrl(url);
                                                                                                   Solution Explorer Team Explorer
    30
                                                                                          Find an element using CSS
    31
                        //Selector to access textbox on the page
                        String selector = "input[name=job_title]";
                                                                                                     Selector
    32
                        var element = driver.FindElement(By.CssSelector(selector));
    33
                        //Type text in that box
    34
                       element.SendKeys("software engineer");
    35
    36
                                                                    Type some text in textbox
    37
                   }
              }
    38
        [}
    39
    40
```

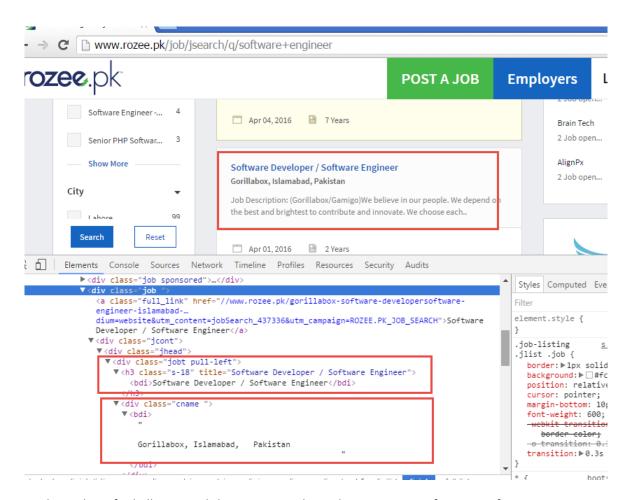

10- If you run above code and click button, you will see that a new browser window will open and will start loading the page. Once page is loaded, you will see that "software engineer" will get typed in highlighted box.

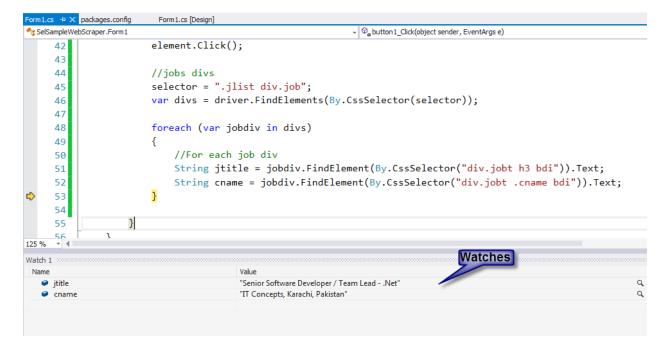

11- Following code finds the button and clicks it.

```
Form1.cs + × packages.config
                        Form1.cs [Design]
selSampleWebScraper.Form1
                                                              → 🗣 button1_Click(object sender, EventArgs e)
                       String url = "http://www.rozee.pk/job/jsearch/q/all";
     26
     27
     28
                       IWebDriver driver = new ChromeDriver();
     29
                       driver.Navigate().GoToUrl(url);
     30
     31
                       //Selector to access textbox on the page
                       String selector = "input[name=job_title]";
     32
                       var element = driver.FindElement(By.CssSelector(selector));
     33
                       //Type text in that box
     34
                       element.SendKeys("software engineer");
     35
     36
                                                                                       Here we are finding
     37
                                                                                            the button
     38
                       //Selector to access Search button
                                                                                          and clicking it
     39
                       selector = "button.btn.search";
     40
                       element = driver.FindElement(By.CssSelector(selector));
                       //Click the button
     41
                       element.Click();
     42
```

12- Now when button is clicked, you will see that URL is updated in browser and results are also filtered now. Here by inspecting our results, we can investigate the HTML of our results. Each result is in "div.job". Inside div, we can see the selectors of Title and company and so on.

13- Her is the code to find all DIVs and then iterating those divs to extract information from it.
